# CHAPTER 1

---

## Grimp

---

Builds a graph of a Python project's internal dependencies.

- Free software: BSD license

**Warning:** This software is currently in beta. It is undergoing active development, and breaking changes may be introduced between versions.

## 1.1 Quick start

Install grimp:

```
pip install grimp
```

Install the Python package you wish to analyse:

```
pip install somepackage
```

In Python, build the import graph for the package:

```
>>> import grimp
>>> graph = grimp.build_graph('somepackage')
```

You may now use the graph object to analyse the package. Some examples:

```
>>> graph.find_children('somepackage.foo')
{
    'somepackage.foo.one',
    'somepackage.foo.two',
}

>>> graph.find_descendants('somepackage.foo')
{
    'somepackage.foo.one',
```

(continues on next page)

(continued from previous page)

```
'somepackage.foo.two',
'somepackage.foo.two.blue',
'somepackage.foo.two.green',
}

>>> graph.find_modules_directly_imported_by('somepackage.foo')
{
    'somepackage.bar.one',
}

>>> graph.find_upstream_modules('somepackage.foo')
{
    'somepackage.bar.one',
    'somepackage.baz',
    'somepackage.foobar',
}

>>> graph.find_shortest_chain(importer='somepackage.foobar', imported='somepackage.foo
↪')
(
    'somepackage.foobar',
    'somepackage.baz',
    'somepackage.foo',
)

>>> graph.get_import_details(importer='somepackage.foobar', imported='somepackage.baz
↪')
[
    {
        'importer': 'somepackage.foobar',
        'imported': 'somepackage.baz',
        'line_number': 5,
        'line_contents': 'from . import baz',
    },
]
```

For the full list of methods, see [Usage](#).

## CHAPTER 2

---

### Installation

---

At the command line:

```
pip install grimp
```

Grimp provides an API in the form of an `ImportGraph` that represents all the internal imports within a top-level Python package. This object has various methods that make it easy to find out information about that package's structure and interdependencies.

### 3.1 Terminology

The terminology around Python packages and modules can be a little confusing. Here are the definitions we use, taken in part from [the official Python docs](#):

- **Module:** A file containing Python definitions and statements. This includes ordinary `.py` files and `__init__.py` files.
- **Package:** A special kind of module that namespaces other modules using dotted module names. For example, the module name `A.B` designates a submodule named `B` in a package named `A`. Packages take the form of `__init__.py` files in a container directory. Packages may contain other packages. *A package is also a module.*
- **Top Level Package:** A package in the root namespace - in other words, one that is not a subpackage. For example, `A` is a top level package, but `A.B` is not.
- **Graph:** A graph [in the mathematical sense](#) of a collection of items with relationships between them. Grimp's `ImportGraph` is a directed graph of all the internal imports contained in a particular top level package.
- **Direct Import:** An import from one module to another.
- **Import Chain:** A chain of imports between two modules, possibly via other modules. For example, if `mypackage.foo` imports `mypackage.bar`, which in turn imports `mypackage.baz`, then there is an import chain between `mypackage.foo` and `mypackage.baz`.

## 3.2 Building the graph

```
import grimp

graph = grimp.build_graph('name_')
```

`grimp.build_graph(package_name)`

Build and return an ImportGraph for the supplied package.

**param str package\_name** The name of the top level package, for example 'mypackage'.

**return** An import graph that you can use to analyse the package.

**rtype** ImportGraph

## 3.3 Methods for analysing the module tree

`ImportGraph.modules`

All the modules in the top level package.

**return** Set of module names.

**rtype** A set of strings.

`ImportGraph.find_children(module)`

Return all the immediate children of the module, i.e. the modules that have a dotted module name that is one level below.

**param str module** The importable name of the module, e.g. 'mypackage' or 'mypackage.foo.one'. This may be any module within the package. It doesn't need to be a package itself, though if it isn't, it will have no children.

**return** Set of module names.

**rtype** A set of strings.

`ImportGraph.find_descendants(module)`

Return all the descendants of the module, i.e. the modules that have a dotted module name that is below the supplied module, to any depth.

**param str module** The importable name of the module, e.g. 'mypackage' or 'mypackage.foo.one'. As with `find_children`, this doesn't have to be a package, though if it isn't then the set will be empty.

**return** Set of module names.

**rtype** A set of strings.

## 3.4 Methods for analysing direct imports

`ImportGraph.direct_import_exists(importer, imported)`

**Parameters**

- **importer** (*str*) – A module name.
- **imported** (*str*) – A module name.

**Returns** Whether or not the importer directly imports the imported module.

**Return type** True or False.

`ImportGraph.find_modules_directly_imported_by(module)`

**Parameters** `module` (*str*) – A module name.

**Returns** Set of all modules in the graph are imported by the supplied module.

**Return type** A set of strings.

`ImportGraph.find_modules_that_directly_import(module)`

**Parameters** `module` (*str*) – A module name.

**Returns** Set of all modules in the graph that directly import the supplied module.

**Return type** A set of strings.

`ImportGraph.get_import_details(importer, imported)`

Provides a way of seeing the details of direct imports between two modules (usually there will be only one of these, but it is possible for a module to import another module twice).

The details are in the following form:

```
[
  {
    'importer': 'mypackage.importer',
    'imported': 'mypackage.imported',
    'line_number': 5,
    'line_contents': 'from mypackage import imported',
  },
  # (additional imports here)
]
```

**Parameters**

- **importer** (*str*) – A module name.
- **imported** (*str*) – A module name.

**Returns** A list of the details of every direct import between two modules.

**Return type** List of dictionaries.

## 3.5 Methods for analysing import chains

`ImportGraph.find_downstream_modules(module, as_package=False)`

**Parameters**

- **module** (*str*) – A module name.
- **as\_package** (*bool*) – Whether or not to treat the supplied module as an individual module, or as an entire package (including any descendants). If treating it as a package, the result will include downstream modules *external* to the supplied module, and won't include modules within it.

**Returns** All the modules that import (even indirectly) the supplied module.

**Return type** A set of strings.

Examples:

```
# Returns the modules downstream of mypackage.foo.
import_graph.find_downstream_modules('mypackage.foo')

# Returns the modules downstream of mypackage.foo, mypackage.foo.one and
# mypackage.foo.two.
import_graph.find_downstream_modules('mypackage.foo', as_package=True)
```

`ImportGraph.find_upstream_modules` (*module*, *as\_package=False*)

**Parameters**

- **module** (*str*) – A module name.
- **as\_package** (*bool*) – Whether or not to treat the supplied module as an individual module, or as a package (i.e. including any descendants, if there are any). If treating it as a subpackage, the result will include upstream modules *external* to the package, and won't include modules within it.

**Returns** All the modules that are imported (even indirectly) by the supplied module.

**Return type** A set of strings.

`ImportGraph.find_shortest_chain` (*importer*, *imported*)

**Parameters**

- **importer** (*str*) – The module at the start of a potential chain of imports between *importer* and *imported* (i.e. the module that potentially imports *imported*, even indirectly).
- **imported** (*str*) – The module at the end of the potential chain of imports.

**Returns** The shortest chain of imports between the supplied modules, or *None* if no chain exists.

**Return type** A tuple of strings, ordered from *importer* to *imported* modules, or *None*.

`ImportGraph.chain_exists` (*importer*, *imported*, *as\_packages=False*)

**Parameters**

- **importer** (*str*) – The module at the start of the potential chain of imports (as in `find_shortest_chain`).
- **imported** (*str*) – The module at the end of the potential chain of imports (as in `find_shortest_chain`).
- **as\_packages** (*bool*) – Whether to treat the supplied modules as individual modules, or as packages (including any descendants, if there are any). If treating them as packages, all descendants of *importer* and *imported* will be checked too.

**Returns** Return whether any chain of imports exists between *importer* and *imported*, even indirectly; in other words, does *importer* depend on *imported*?

**Return type** `bool`

## 3.6 Methods for manipulating the graph

`ImportGraph.add_module` (*module*)

Add a module to the graph.

**Parameters** `module` (*str*) – The name of a module, for example `'mypackage.foo'`.

**Returns** `None`

`ImportGraph.add_import` (*importer*, *imported*, *line\_number=None*, *line\_contents=None*)

Add a direct import between two modules to the graph. If the modules are not already present, they will be added to the graph.

**Parameters**

- **importer** (*str*) – The name of the module that is importing the other module.
- **imported** (*str*) – The name of the module being imported.
- **line\_number** (*int*) – The line number of the import statement in the module.
- **line\_contents** (*str*) – The line that contains the import statement.

**Returns** `None`

`ImportGraph.remove_import` (*importer*, *imported*)

Remove a direct import between two modules. Does not remove the modules themselves.

**Parameters**

- **importer** (*str*) – The name of the module that is importing the other module.
- **imported** (*str*) – The name of the module being imported.

**Returns** `None`

Contributions are welcome, and they are greatly appreciated! Every little bit helps, and credit will always be given.

### 4.1 Bug reports

When [reporting a bug](#) please include:

- Your operating system name and version.
- Any details about your local setup that might be helpful in troubleshooting.
- Detailed steps to reproduce the bug.

### 4.2 Documentation improvements

Nameless could always use more documentation, whether as part of the official Nameless docs, in docstrings, or even on the web in blog posts, articles, and such.

### 4.3 Feature requests and feedback

The best way to send feedback is to file an issue at <https://github.com/seddonym/grimp/issues>.

If you are proposing a feature:

- Explain in detail how it would work.
- Keep the scope as narrow as possible, to make it easier to implement.
- Remember that this is a volunteer-driven project, and that code contributions are welcome :)

## 4.4 Development

To set up *grimp* for local development:

1. Fork [grimp](#) (look for the “Fork” button).
2. Clone your fork locally:

```
git clone git@github.com:your_name_here/grimp.git
```

3. Create a branch for local development:

```
git checkout -b name-of-your-bugfix-or-feature
```

Now you can make your changes locally.

4. When you’re done making changes, run all the checks, doc builder and spell checker with `tox` one command:

```
tox
```

5. Commit your changes and push your branch to GitHub:

```
git add .
git commit -m "Your detailed description of your changes."
git push origin name-of-your-bugfix-or-feature
```

6. Submit a pull request through the GitHub website.

### 4.4.1 Pull Request Guidelines

If you need some code review or feedback while you’re developing the code just make the pull request.

For merging, you should:

1. Include passing tests (run `tox`)<sup>1</sup>.
2. Update documentation when there’s new API, functionality etc.
3. Add a note to `CHANGELOG.rst` about the changes.
4. Add yourself to `AUTHORS.rst`.

### 4.4.2 Tips

To run a subset of tests:

```
tox -e envname -- pytest -k test_myfeature
```

To run all the test environments in *parallel* (you need to `pip install detox`):

```
detox
```

---

<sup>1</sup> If you don’t have all the necessary python versions available locally you can rely on Travis - it will run the tests for each change you add in the pull request.  
It will be slower though ...

## CHAPTER 5

---

### Authors

---

- David Seddon - <http://seddonym.me>

### 6.1 0.0.1 (2018-11-05)

- Release blank project on PyPI.

### 6.2 1.0b1 (2018-12-08)

- Implement core functionality.

### 6.3 1.0b2 (2018-12-12)

- Fix PyPI readme rendering.

### 6.4 1.0b3 (2018-12-16)

- Fix bug with analysing relative imports from within `__init__.py` files.
- Stop skipping analysing packages called `migrations`.
- Deal with invalid imports by warning instead of raising an exception.
- Rename `NetworkXBackedImportGraph` to `ImportGraph`.

### 6.5 1.0b4 (2019-1-7)

- Improve repr of `ImportGraph`.
- Fix bug with `find_shortest_path` using upstream/downstream the wrong way around.

## 6.6 1.0b5 (2019-1-12)

- Rename `get_shortest_path` to `get_shortest_chain`.
- Rename `path_exists` to `chain_exists`.
- Rename and reorder the kwargs for `get_shortest_chain` and `chain_exists`.
- Raise `ValueError` if modules with shared descendants are passed to `chain_exists` if `as_packages=True`.

## CHAPTER 7

---

### Indices and tables

---

- `genindex`
- `modindex`
- `search`
